1. Buying an Item

The customer gets a price for an item and buys and item

Objective	When item is chosen the correct price is shown on the seven-segment display, then when they put money in the machine you show the amount that they have put in, then when they dispense the item, the board clears	
Results	The customer can put in the correct amount of money, the items price show correctly, and the item is dispensed without failure	
Actors	Basic understanding of how the system works, but other than that it should hopefully be straight forward	
Related use cases	They all play off of each other. Purchasing an item with an oversized balance, choosing multiple items before buying one, etc.	
Trigger	Someone puts the correct amount of money given by the saved value, and vends the item	
Stakeholders	The owner of the machine is interested in this as well as the customer who is buying an item from the machine	
Resources	Quartus and the SoC Series V Board	
Assumptions	A working setup with the seven-segment display, working money switches, working RAM set up for items and the working keypad as well	
Post-condition	The system itself shouldn't change	
Frequency	Hopefully as often as possible	
Mission Priority	The highest importance. This is the mist basic of basic use cases that is necessary for the system to work	
Safety Priority	I hope there is no safety concern	
Flow of events	**Step #**	**Action**
	1.	Customer chooses item that they want
	2.	Price of chosen item displays on 7-seg display
	3.	Customer inputs money values through the switches
	4.	The customer hits the vend button(button3)

	5.	Customer "receives" item and no change should be returned
Hazard/ Result /Mitigation	• If this case is done incorrectly, the entire system is likely incorrect or not working to specifications	
Requirements from Use Case	• Output value of chosen item and the cost of said item • Input value of money and output the value that is inputted • Give Item:)
