2. Multiple Prices Before Buying

The customer gets multiple prices on items before selecting one and buying it

Objective	When the customer selects the first through the nth item, all prices will show up on the 7-segement displays as intended, with correct stored prices and product numbers. When they finally choose their item and select to "pay," they amount of money they put into the system is correct and the change if necessary is given correctly	
Results	The customer can choose their item, and the result should give them the correct price of their chosen item and show them how much money they put in	
Actors	Basic understanding of how the system works, but other than that it should hopefully be straight forward	
Related use cases	Some of the related use cases are just basic buying an item and anywhere they are straight up paying for an item. If the system gets to the end with either exact payment or with change, if the system works to the result, the use cases are similar	
Trigger	Flipping through multiple different items before choosing their item	
Stakeholders	The owner of the machine is interested in this as well as the customer who is buying an item from the machine	
Resources	Quartus and the SoC Series V Board	
Assumptions	A working setup with the seven-segment display, working money switches, working RAM set up for items and the working keypad as well	
Post-condition	The system itself shouldn't change, but going through the different items should bring up the different items and their prices correctly	
Frequency	I would assume not too much, but it can occur commonly at some points in time depending on the customer	
Mission Priority	This is high importance because this could be customer to customer	
Safety Priority	I hope there is no safety concern	
Flow of events	**Step #**	**Action**
	1.	Customer browses the catalog of items
	2.	Customer chooses item that they want

	3.	Price of chosen item displays on 7-seg display
	4.	Customer inputs money values through the switches
	5.	The customer hits the vend button(button3)
	6.	Customer "receives" item and no change should be returned
Hazard/ Result /Mitigation	• If this case is done incorrectly, the entire system is likely incorrect or not working to specifications	
Requirements from Use Case	• Output value of chosen item and the cost of said item as well as other items when the customer is browsing the selection • Input value of money and output the value that is inputted • Give Item 😊 • If there is change, also include that price on the 7-segment
